

Module 10

Modern Navigation Systems

Solving for Time

Module 10B

The 1804 Nautical Almanac

Summary of Module 10

- Students will learn how to determine time from celestial measurements, and about the relationship between index and time offset errors for sextant and GPS observations, respectively. (10A)
- **Students will learn how to read and use Nevil Maskelyne's 1804 Nautical Almanac, the predecessor to today's modern Nautical and Air Almanacs. (10B)**
- Students will use Newton's method to determine latitude, learn how to relate the lunar distance to GHAY in order to determine GMT/UTC time and longitude, and learn how to compute the corrections for parallax using Richharia's equations. (10C)
- Students will use these new skills to analyze actual celestial observation data from the Lewis and Clark expedition. (10D)

The Nautical Almanac

- Nevil Maskelyne created the world's first nautical almanac.
- It has been updated and published ever since, leading to the 2015 Nautical Almanac that is required for this course.

Who was Neville Maskelyne?

- Nevil Maskelyne was the Royal Astronomer in England in the late 18th and early 19th centuries
- He provided considerable guidance and assistance to the Mason-Dixon survey
 - In Danson's book, Maskelyne is portrayed as a hero
- At the same time, Maskelyne was actively involved in the controversy over John Harrison's attempt to win the Longitude Prize by building a precision chronometer that could keep time aboard ship to an accuracy of better than 2 minutes over a span of three months
 - In Sovel's book, Maskelyne is portrayed as a villain.

The 1804 Almanac

- At Thomas Jefferson's instruction, Lewis and Clark took a sextant and a copy of the 1804 Almanac on their expedition.
- The Almanac has been copied and republished, and can be purchased on Amazon.
- The entries from the Almanac for June 1804 are provided in the slides that follow.
- Note the ubiquitous use of the middle case “s”, which in turn looks like a script “f” and an integral sign. For example, “right afcenfion” means “right *afcenfion*” = “right *a|cen|fion*” until about 1804, when it was replaced by “right ascension”.

This page shows the relative positions of the four largest moons of Jupiter . Since the orbital radius of each moon is different, so are their orbital periods. Since Jupiter is so far away from earth, parallax isn't an issue. Hence, the view of the moons is the same from different points on earth, and the relative positions of the different moons are like the hands on a clock.

Viewing Jupiter's largest moons

Seeing Jupiter's Moons with the Unaided Eye.

Left image, Jupiter at 11:00 pm on Monday 27 September; Right image, Orientation of the Moons, Callisto will be to the right and below Jupiter, Ganymede will be up and to the left.

It is not commonly known, but Jupiter's moons are bright enough to be seen with the unaided eye. However, they are so close to bright Jupiter that the intensity of its light (and the optical imperfections of our eyes), makes it impossible to see them except under special circumstances).

At opposition bright Ganymede (mag 4.6) and Callisto (mag 5.7) can be far enough away from Jupiter to see when they are at their maximum distance from Jupiter in their orbits. Jupiter's light will still probably obscure them for all but those with the most sensitive vision. However, if you use a wall or post to just block out Jupiter's light, you should see them pop into view.

Assignment 10.2

1. Compare your result for the equation of time correction from assignment 10.1 with the corresponding entry in the 1804 Almanac.
2. Compare your result for the lunar distance computation from assignment 10.1 with the corresponding entry in the 1804 almanac.
3. Plot the lunar distance as a function of time for June 1804 on the same graph as a plot of GHAY for the same period of time.
4. Comment on your results with respect to the use of the lunar distance for determining GHAY .
